Bar Charts in ggplot2

1 Background

While `ggplot2`, and the ideas of an underlying *"grammar of graphics"*, make some kinds of graphing easier, `ggplot2` can make other types of graphing more difficult.

One often tricky type of graph is the bar chart. I have come to think that part of the difficulty with thinking about bar charts in `ggplot2` is that sometimes **three very different types of bar charts look similar.**

2 Introduction

Many bar charts look **something like** the bar chart below.
However, there are actually three slightly separate underlying *"grammars of graphics"* that might underlie a bar chart:

1. Bar charts where the height of the bars is the **number of observations** in each category.
2. Bar charts where the height of the bars is the **average value of the y variable** for that category.
3. Bar charts where the height of the bars is the **actual value of the y variable** for that **individual observation.**
Let's look at each situation in turn, since each situation demands a slightly different syntax.

3   Our Data

x	y
1	10
2	5
2	9
3	8
3	9
3	10

4   Bar charts where the height of the bars is the number of observations in each category.
```
library(ggplot2)

ggplot(mydata, # the data that I am using
       aes(x = x)) + # 'aesthetic' only includes x
  geom_bar(fill = "royalblue") # using bars to graph
```

4.1   Stacked Bar Chart

A simple change to the above aesthetic yields a stacked bar chart. Note that *fill* now becomes part of the *aesthetic* so that color fill differentiates the parts of the bar.

```
ggplot(mydata, # the data that I am using
       aes(x = 1, # x is 1
           fill = factor(x))) + # fill is x as a factor
  geom_bar() + # using bars to graph
  scale_fill_discrete(name = "x") # modify name of legend
```

We then return to an unstacked bar chart to consider the syntax for adding labels.

4.2   Add Labels

Adding labels requires adding an extra geom, geom_text. We have to add a new, non-intuitive aesthetic to geom_text to tell it where the labels are located, and that they represent the count of observations in each category.

```
ggplot(mydata, # the data that I am using
       aes(x = x)) + # 'aesthetic' only includes x
  geom_bar(fill = "royalblue") + # using bars to graph
  geom_text(stat = "count",
            aes(label = ..count.., # text of the label
                y = ..count.. + .5), # location of the label
            size = 5) # size of the label
```
5 Bar charts where the height of the bars is the average value of the y variable for that category.

```
library(ggplot2)

ggplot(mydata, # the data that I am using
       aes(x = x, # 'aesthetic' includes x
           y = y)) + # and y
  stat_summary(fun.y = mean, # summarizing y
               geom = "bar", # with bars
               fill = "royalblue") +
  labs(y = "average y")
```

5.1 What About a Line Chart?

A line chart requires the addition of group to the aesthetic, and the use of a different geometry.

```
ggplot(mydata, # the data that I am using
       aes(x = x,
           y = y,
           group = 1)) + # add 'group'
  stat_summary(geom = "line", # with line
               fun.y = mean,
               color = "royalblue")
```

6   Bar charts where the height of the bars is the actual value of the y variable for that category.

Here is where things get complicated. We try something we've tried before, but now adding *y* to the aesthetic.

```
library(ggplot2)

ggplot(mydata, # the data that I am using
       aes(x = x, # 'aesthetic' includes x
           y = y)) + # and y
  geom_bar()
```

This generates the following error message:

```
Error: stat_count() must not be used with a y aesthetic.
```

The reason that we are getting this error is that, by default, geom_bar() is trying to **count up** the number of *x* values, and in **counting up** the number of *x* values, geom_bar() does not know what to do with the *y* value.

So we change this...

```
library(ggplot2)

ggplot(mydata, # the data that I am using
       aes(x = x, # 'aesthetic' includes x
           y = y)) + # and y
  geom_bar(stat = "identity", # use ACTUAL y for bar height
           fill = "royalblue")
```
If we go back and look at our data, we remember that we have some duplicate *x*'s,

1, 2, 2, 3, 3 and *3*

so some of the bars are actually **over-printing.**

We can see this if we make the bars semi-transparent, and outline the bars with a different color.

```
library(ggplot2)

ggplot(mydata, # the data that I am using
       aes(x = x,
           y = y)) + # 'aesthetic' only includes x
  geom_bar(stat="identity", # use ACTUAL y for bar height
           fill = "royalblue", # fill
           color = "red", # outline
           alpha = .5) # transparency
```

7   Thinking Through The Issue

What is the solution? We may want to go back and look at our data to ensure that if we are using the actual *y* value for the height of the bars that we do **not** have duplicate values of *x* in our data.

Or, we may want to have the bars represent the **average value of y** rather than the **actual values of y,** as we did in one of the examples above.
8   Of Course The Problem Wouldn't Come Up If We Had Different Data, Without Those Duplicate *x* Observations

xREVISED	yREVISED
1	10
2	5
3	8

8.1   And Then A Bar Chart Is Easy

```
library(ggplot2)
```

```
ggplot(mydataREVISED, # the data that I am using
       aes(x = xREVISED, # 'aesthetic' includes x
           y = yREVISED)) + # and y
  geom_bar(stat = "identity", # use ACTUAL y for bar height
           fill = "royalblue")
```

8.2   A Line Chart Is Easy Too
```
library(ggplot2)
```

```
ggplot(mydataREVISED, # the data that I am using
       aes(x = xREVISED, # 'aesthetic' includes x
           y = yREVISED)) + # and y
  geom_line(stat = "identity", # use ACTUAL y for bar height
            color = "royalblue")
```

9   And Then There Are Pie Charts

In some ways it is confusing, and in some ways it is helpful, that according to the underlying *grammar of graphics* in ggplot2, pie charts can be seen as **bar charts that use polar coordinates.** With that in mind, we take some of our earlier code, and add coord_polar().

In the code below, I need to ensure that ggplot2 sees *x* as a **factor**, and to use *x* as a **fill. Fill** is a crucial piece of information in a pie chart.

```
library(ggplot2)
```

```
ggplot(mydata, # the data that I am using
       aes(x = 1,
           fill = factor(x))) + # x is now the fill
  geom_bar() + # using bars to graph
  coord_polar(theta = "y") + # polar coordinates
  theme_void() # get rid of distracting numbers
```

Unfortunately, pie charts are deprecated in some circles, so support for pie charts is not very strong in `ggplot`. It is certainly possible to create a pie chart in `ggplot`, but adding labels to a pie chart ends up being very very difficult.

9.1   Pie Chart With Better Colors

```
library(ggplot2)

library(viridis) # wonderful colors

ggplot(mydata, # the data that I am using
       aes(x = 1,
           fill = factor(x))) +
  geom_bar() + # using bars to graph
  coord_polar(theta = "y") + # polar coordinates
  scale_fill_viridis(discrete = TRUE,
                     name = "x") + # name for legend
  theme_void()
```
10   Bar Chart With Better Colors

Up until now, we have had a *minimalist* vision of bar charts, where every bar is the same color, because color would not add **additional information**, over and above the information contained in the position on the *x* axis. However, for the sake of design, we may also choose to add some color to our bar charts. ggthemes, ggthemr and viridis are all ways of adding color to ggplot graphs.

```
library(ggplot2)

library(viridis) # wonderful colors

ggplot(mydata, # the data that I am using
       aes(x = x, # x is on the x axis
           fill = factor(x))) + # x is also a factor for fill
  geom_bar() + # using bars to graph
  scale_fill_viridis(discrete = TRUE,
                     name = "x")
```

11   More Examples
